intermediate metabolites in the urine, the stiffness of the muscles, and other symptoms, lead us to believe that such products of metabolic activity are inefficiently removed from the system. The introduction of more fluid in this manner can be expected to remedy this deficiency of excretion, which is often, we hold to be of far greater importance than deficiency of nutrition.

Repeated experience contradicts the popular conviction that large quantities of food must be taken in order to "feed the system." In this instance, soldiers bearing heavy clothing and equipment have frequently marched for many hours with no food, provided that a sufficiency of water is available. Experiments on animals, too, show that external work can be performed for some days on a water diet only.

These facts serve to justify us in advising the consumption of little or no solid food during the race; we think that in this way the gastric disturbances would be entirely obviated. In order to avoid the depressing mental effect consequent upon the withholding of all food, allum water, or some such preparation might be given. This would only be as a concession to the men's preconceived ideas, and not with the object of providing nourishment. The use of a little alcohol as a readily diffusible and oxidizable stimulant in the last stages of the race seems to be free from objection.

Although a walking race such as this seems to involve far less risk of over-exertion than has hitherto been supposed, it has, in our opinion, much less satisfactory than running, and infinitely less so than a contest of the nature of a football match, which brings into play the full exercise of every faculty as well as that of every muscle. It appeared, indeed, that endurance was the most potent factor in determining a competitor's position at the finish, and it quickly became evident that to estimate a man's chances from consideration of his physical appearance was absolutely impossible. This conclusion was shared with us by several physiologists who were present.

The mental factor in contests of this kind is worthy of careful consideration, the man of fine sensibility needing enormous self-control in order to compete on equal terms with the man of blunter temperament. This was recognized by the Committee of the Royal Society, and was also exemplified in the obvious mental and physical improvement which followed the rising of the sun.

The expenses of this investigation were defrayed from the British Medical Association's grant to Dr. Pembrey, who has added to the many other kindnesses shown to us by suggesting the lines which the present research should follow. We are also greatly indebted to Mr. A. Sanderson for valuable assistance in many of these observations.

REPORT CXIX.

AURICULAR FIBRILLATION: A COMMON CLINICAL CONDITION."

By THOMAS LEWIS, M.D.LOND, D.SC.WALS.

(From the Research Laboratories of University College Medical School.)

[A Preliminary Communication.] It is well known that in the late stages of mitral stenosis, and in cases of general cardio-vascular degeneration, the pulse is frequently continuously and extremely irregular. The nature of this irregularity is remarkable in that the radial and cardiographic curves it defies analysis. The nature of the two curves has given rise to the term pulsus irregularis perpetuus, and it has been supposed that the rhythm of the heart producing it has its origin in the node of Tawara (termed the "midnight rhythm"). The condition is extremely common.

Facts are now at my disposal permitting of two conclusions:

I. That a rhythm arising in the neighbourhood of the node of Tawara is an entirely different clinical picture. This conclusion is based upon a detailed examination (photographic and electrocardiographic) of a case of paroxysmal tachycardia, in which it can be demonstrated that auricle and ventricle contract together. This rhythm is a rare clinical phenomenon.

II. That the irregular pulse of mitral stenosis, etc., already referred to, is due to fibrillation of the auricle.

The second conclusion is based upon the following evidence:

1. The clinical irregularity presented by arterial and heart apex curves is unique. The rhythm is entirely disorderly, and the sizes of the beats do not correspond to the pulses which present this kind of irregularity. Fibribillation of the auricle results in a similar action of the ventricle, and its action under these circumstances is unique experimentally.

2. Electrocardiograms taken from patients exhibiting the irregularity show a number of irregular waves, apart from the ventricular curve; they are more clearly defined in diastole. They are found in no other disorder of the heart's action. They disappear when, in a paroxysmal case, the irregularity vanishes, and any observation may be as a result of some part of the heart wall. Cardiographic curves give no evidence of such a disordered action in the ventricle. Fibribillation of the auricle yields curves which are identical in every respect, and no such curves have been noted in the other experimental means. Further, the waves on the experimental electrocardiograms can be shown to correspond to the fibrillary movements in the auricle, by means of synchronous tracings.

The venous curves in the clinical irregularity is of the venricular type; all the prominent waves occur during ventricular systole, and there is no wave corresponding to a normal auricular contraction. The same statement applies to the venous curves in fibrillation of the auricle. The clinical and experimental curves are of the same nature.

The facts point clearly to the conclusion that the irregularity in question is the result of auricular fibrillation, and the conclusion affords an explanation of several otherwise inexplicable facts. It provides us with a rational understanding of the disorderly nature of the ventricular rhythm, for it is dependent upon the irregular auricular movements. It explains the slowing which is obtained by digitalis in those instances in which an auricular paroxysm is known to be frequently impaired—namely, in cases of rheumatic origin; for digitalis is known to increase the hindrance to the passage of the impulses where conduction is already damaged. Further, it explains the difference between the two types of irregularity considered, and that due to what is termed "nodal extra-systole." It is in accord with the now generally accepted fact that the rhythm is supraventricular in origin; it harmonizes equally well with the evidence that the auricle is active in furious movement when the irregularity is present—for example, the auricular hypertrophy found at autopsy in cases succumbing with the irregularity present and of long duration. Finally, it suggests a plausible explanation of so-called "nodal bradycardia." This condition may be regarded as auricular fibrillation and spontaneous auriculo-ventricular heart-block. The full evidence, including the curves, will be placed on record at an early date.

The Herbert Spencer Lecture before the University of Oxford will be delivered by Dr. G. C. Bourne, Linacre Professor of Comparative Anatomy, who has taken for his subject, "Herbert Spencer and animal evolution."

A REUTER'S telegrams from Peking states that considerable progress has been made in the suppression of opium smoking in the northern provinces and in Yunnan and Kiangtung, less in the central provinces, and very little in Szechuan, Kwchau, and Shensi.

The resolution adopted at the meeting of medical practitioners on November 10th, organized by the Chelsea Division of the British Medical Association, as to payment to medical practitioners from the Fulham guardians at a meeting on November 9th, but its full discussion was adjourned to a later date. Meanwhile it may be said that one member of the council had not received medical men's calls, and that consequences of the Act which gave them a definite claim upon guardians in this connexion, it was the undoubted duty of guardians to guarantee the payment of their fee to any medical man called in to save life during childbirth.
